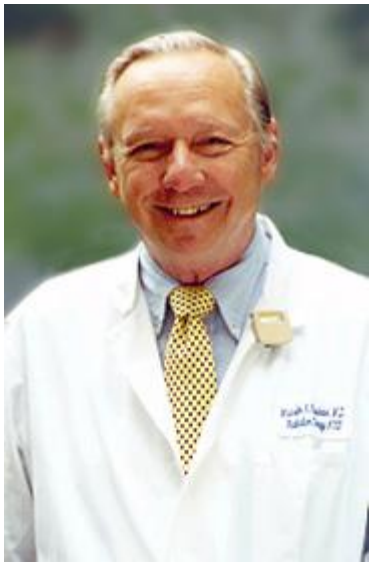
Extended field radiation therapy for carcinoma of the prostate: a progress report
Bagshaw MA.
Cancer Chemother Report 59: 165-73, 1975.



- Radiotherapeutic treatment of prostatic carcinoma with pelvic node involvement.

  Bagshaw MA.

  Urol Clin North Am 11: 297-304, 1984.

  Survival with N+: 20% “In spite of this relatively low level of survival, the firm documentation of survival without evidence of lymph node disease in 9 out 60 patients is ample justification for irradiation of regional lymphatics in these high-risk patients.

CRITICAL REVIEW

PELVIC NODAL RADIOTHERAPY IN PATIENTS WITH UNFAVORABLE INTERMEDIATE AND HIGH-RISK PROSTATE CANCER: EVIDENCE, RATIONALE, AND FUTURE DIRECTIONS

LISA K. MORIKAWA, M.D.,*† AND MACK ROACH III, M.D.‡

*The University of Texas, M. D. Anderson Cancer Center, †Memorial Sloan-Kettering Cancer Center, ‡University of California San Francisco (UCSF), Helen Diller Family Comprehensive Cancer Center

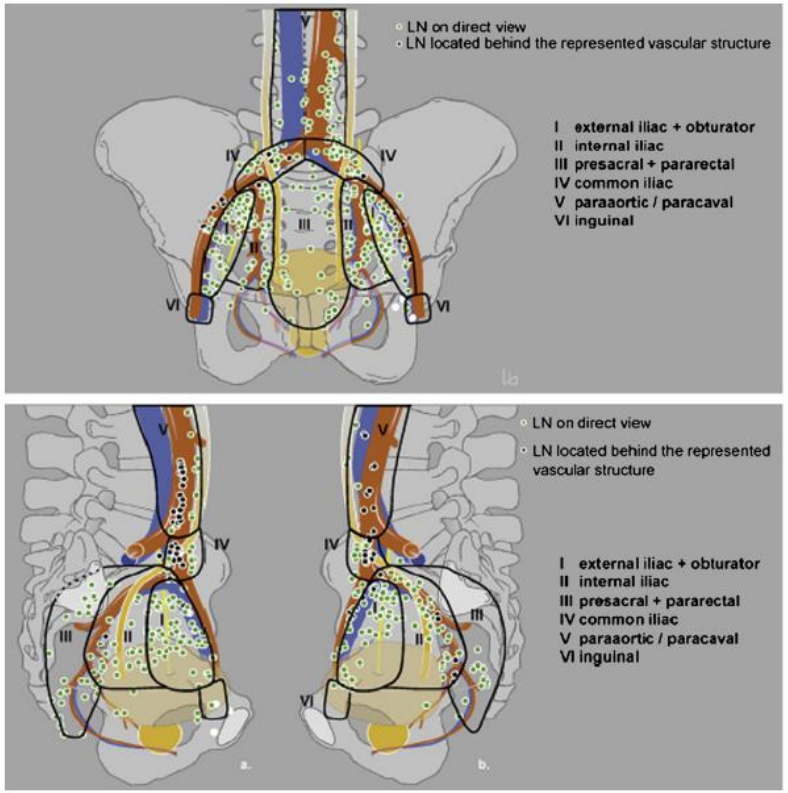

Fig. 1. Anteroposterior (A) and lateral (B) lymphatic drainage maps based on intraprostatic injections of technetium followed by single photon emission tomography (SPECT) combined with either computed tomography or magnetic resonance imaging fusion confirmed by surgery. Lymph nodes were color coded and subsequently transferred into a template projection of the pelvis according to their relation with vascular structures. From Mattei *et al.* (45).

Table 1. Contemporary trials comparing outcomes with whole pelvic vs. prostate only external beam radiotherapy (from Roach *et al.*)58

First Author	Institution		Key Findings	
Seaward	University of California, San Francisco	Retrospective single institutional analysis of patients undergoing prostate only or WPRT with and without hormonal therapy.	WPRT defined at superior border L5-S1. Noted WPRT associated with improved PSA control rate. Greatest benefit seen for those with risk between 15 and 30%.	↑ PSA
Pan	University of Michigan	Compared men treated with definitive 3D-CRT (n = 1,832) divided into three categories based on the estimated risk (Partin table) of LN involvement: 0–5%; >5–15%; and >15%.	Significant benefit for whole pelvic radiotherapy in men with risk of lymph node involvement of 5–15% with an improved 2-year PSA control rate, 90.1% vs. 80.6% (p = 0.02).	↑ PSA
Roach	RTOG	Phase Randomized Trial III (n ~1,200) comparing sequence of hormonal therapy and role of whole pelvic vs. prostate only radiotherapy. Primary endpoint: PFS including PSA, clinical failure, death from any cause	WPRT associated with improvement in PFS when preceded by CAB but not when administered before CAB	↑ PFS
Jacob	Fox Chase Cancer Center	Retrospective analysis patients with risk +LN >15% treated with "whole" pelvic radiotherapy vs. partial pelvic radiotherapy, or prostate only fields (n = 420). Concluded radiation dose was the major determinant of PSA control in patients with a lymph node risk >15%, with no benefit to pelvic radiotherapy or hormonal therapy	None of the patients received WPRT (defined as superior border L5-S1) as defined by RTOG 9413. All patients' pelvic fields would have been included in prostate only arm of RTOG 9413	↔
Spiotto	Stanford	Retrospective analysis of post op patients undergoing prostate only or WPRT with and without hormonal therapy.	Use of WPRT associated with an improvement in PSA control rate in the setting of salvage radiotherapy with greatest benefit seen in patients with adverse features	↑ PSA
Pommier	Multi-Center French Trial	444 patients with T1b-T3N0M0 randomized to 66–70 Gy to prostate ± 46 Gy to pelvis with the superior border set to S1/S2. RT preceded by 4–8 months of CAB is some "high-risk" patients (≥T3, GS ≥7, or PSA ≥3× normal). Most patients had LN risk <15% (55%) using Roach formula	None of the patients received WPRT (defined as top L5-S1) most were low risk for lymph node involvement (median PSA 12, ~25% T3, and ~10% GS 8–10), and some did not receive CAB	↔
Da Pozzo	Italy	Retrospective study 250 consecutive patients with + nodes. Compared outcomes in 129 men treated with WPRT (51.6%) and ADT and 121 patients (48.4%) received ADT alone	Multivariable analysis use of WPRT and the number of + lymph nodes major predictors of PSA control (p = 0.002 and p = 0.003) and cause specific survival (p = 0.009 and p = 0.01)	↕
Aizer	Yale	Retrospective review of 277 consecutive patients with estimated risk of lymph node involvement ≥15%	After adjusting for other factors WPRT group had improved 4-year biochemical control rate (69.4% vs. 86.3%).	↑ PSA
Milecki	Greater Poland Cancer Center	Retrospective analysis including men with high risk disease (n = 162) with and without WP RT.	The 5-year actuarial cause specific survival (CSS) were A = 90% and B = 79% (p = 0.01) and PSA control rates 52% versus 40% (p = 0.07), respectively.	↑ PSA

Abbreviations: ADT = androgen deprivation therapy; CAB = combined hormonal blockade; GS = Gleason score; LN = lymph node; PFS = progression-free survival; PSA = prostate-specific antigen; RTOG = Radiation Therapy Oncology Group; 3D-CRT = three-dimensional conformal radiotherapy; WPRT = whole pelvic radiotherapy.

[c] Department of Radiology and Biomedical Imaging, Box 0628, 505 Parnassus Avenue, University of California, San Francisco, CA-94143-0628, San Francisco, United States

Table 2
Summary of investigational imaging tools for patients with occult nodal involvement from prostate cancer in the context of radiation oncology.

	Requirements	Advantages	Disadvantages
MR Lymphangiography with USPIO	-Conventional MR scan -At least 1.5T IV injection of ferumoxtran-10 24–36 h before	-Non invasive -High sensitivity (82–90%) and specificity (96–98%) -Reproducible results -Detection of LNM ⩽ 2 mm -Better contrast with soft tissues and LN border delineation	-High false positive rate -Lack of FDA and EMA approval -Fusion CT/MR for treatment planning
Sentinel node SPECT/CT	-TRUS-guided injection of Technetium in each lobe 1–3 h before -SPECT camera combined with a CT scanner	-Visualization of lymph flow pathway -Fusion CT/CT for treatment planning	-Minimally invasive -It shows where are the SLN but not whether SLN are involved -Assumes that prostate cancer is not a systemic disease -Prostate must not be removed -Bulky N+(PSA > 20 ng/mL) may compromise Technetium uptake -May miss LNM or nodes distant from the camera
Choline-based PET/CT	-PET camera combined with a CT scan -Injection of the tracer 2 min. beforehand -Cyclotron needed for 11C-labeled choline tracers	-Non invasive -High specificity (96%) and NPV (92%) -Visualize distant nodes and extranodal metastatic disease (one-stop diagnostic procedure) -Fusion CT/CT for treatment planning	-Low sensitivity (vs. SN dissection or ePLND) -Low detection rate if PSA < 4 ng/mL -Distribution of tracers to institution depends on half life of each tracer -Low spatial resolution of cameras (LNM ⩾ 5 mm only) -Lack of FDA approval

LNM: Lymph Node Metastasis; LN: Lymph Nodes; FDA: Food and Drug Administration; European Medical Agency; PSA: Prostate Specific Antigen; SLN: Sentinel Lymph Node; ePLND: extensive Pelvic Lymph Node Dissection; CT: computed tomography; MR: Magnetic Resonance imaging; T: Teslas; TRUS: Trans-Rectal Ultra-Sonography.

MR Lymphoangiography vs PET choline vs SPECT - Sentinel node

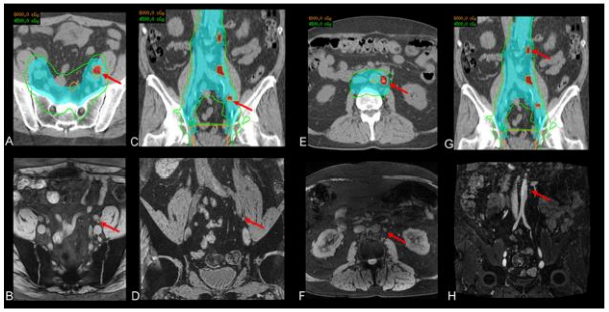

Fig. 1. Magnetic Resonance Lymphangiography Guided Treatment for Prostate Cancer. Legend: This figure shows a treatment plan and associated magnetic resonance lymphangiography (MRL) for a patient with recurrent prostate cancer. For dose to nodes identified by MRL can be boosted to 6000 cGy. In the currently presented patient, multiple lymph nodes involving the left external iliac and para-aortic areas were identified. The clinical target volume was therefore extended from the standard whole pelvic nodal volume to include the para-aortic nodes. Doses to target volumes are depicted as 6000 cGy (orange) and 4500 cGy (green). (A) Planning CT (axial) with pelvic nodal volume depicted in cyan and an involved external iliac node, detected by MRL in red. (B) MRL (axial) with involved external iliac node identified with a red arrow. (C) Planning CT (coronal) showing the same involved external iliac node as seen in (A) and (B). (D) MRL (coronal) with the same involved external iliac node shown in (A) and (B) identified with a red arrow. (E) Planning CT (axial) with para-aortic nodal volume depicted in cyan and an involved para-aortic node, detected by MRL in red. (F) MRL (axial) with involved para-aortic node identified with a red arrow. G) Planning CT (coronal) showing the same involved para-aortic node as seen in (E) and (F). (H) MRL (coronal) with the same invo

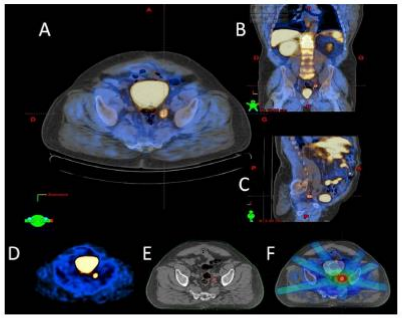

Fig. 2. Fluorocholine (18F) Positron Emission Tomography (PET) combined with Computed Tomography (CT) guided treatment for isolated nodal relapses after prostatectomy. Legend: This figure shows a treatment plan and associated how (18F) PET/CT for a patient with recurrent prostate cancer in a single node. In the currently presented patient, a single left iliac node was identified. Treatment was delivered under stereotactic conditions. In the current presented patient, a biochemical failure occurred 61 months after radical prostatectomy. Initially, the pathologist has reported an adenocarcinoma, Gleason 7 (3 + 4), staged pT3 R0, pN0. After the PSA rose up, the patient underwent a salvage radiation to the prostatic fossa. FCH PET/CT demonstrated isolated pararectal uptake. A salvage PET-guided IMRT delivered 66 Gy (5 × 2 Gy/week). Two years after the treatment, the patient is still controlled without any androgen deprivation therapy. (A) (18F) PET/CT (axial) with the involved iliac node, as detected on Fluorocholine PET/CT in yellow. (B) (18F) PET/CT (coronal) with involved external iliac node identified with a red arrow. (C) (18F) PET/CT (sagittal) showing the (B) to

Table 3

The evolving place of conventional and investigational imaging modalities in the work-up of prostate cancer patients with respect to different situations.

	Imaging available for lymph node staging					
	CT	MRI	PSMA-based SPECT	MRL (USPIO)	SPECT/CT	Choline PET
High-risk prostate cancer requiring whole pelvic radiotherapy	+	+	+	+++	+++	+++
Postoperative radiotherapy (Undetectable PSA)	+	+	–	++	–	–
Postoperative radiotherapy (Detectable or rising PSA)	+	+	–	++	–	++
Rising PSA after external radiotherapy and/or brachytherapy	+	+	–	++	++	++

CT: Computed Tomography scan; MRI: Magnetic Resonance Imaging; MRL: Magnetic Resonance Lymphangiography with Ultra Superparamagnetic Particles of Iron Oxide; SPECT/CT: Single Photon Emission Computed Tomography/Computed Tomography; PET: Positron Emission Tomography; –: not recommended; +: not optimal; ++: recommended; +++: highly recommended.

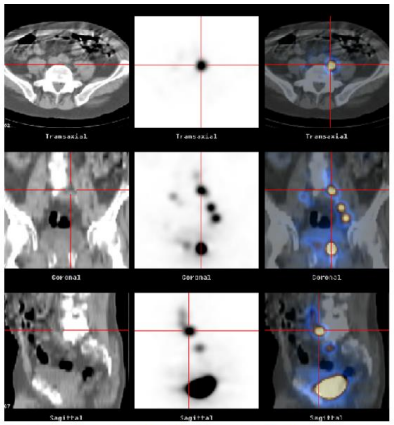

Fig. 3. 3D SPECT/CT imaging example with three sentinel lymph nodes (iliac left), radionuclide filled bladder (courtesy of Ute Ganswindt, with permission[100]). Legend: Transmission and emission scans were acquired 1.5 to 3 h after intraprostatic injection of 150 to 362 (median 205) MBq 99mTc-nanocolloid (Nanocoll, GE Healthcare Buchler GmbH, Braunschweig, Germany) depending on the individual prostate volume, followed by an anatomic-functional image fusion (SPECT/CT). The injection was performed in both lobes of the prostate.

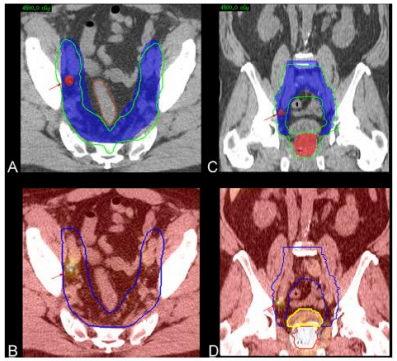

Fig. 4. Sentinel Lymphangiography Guided Treatment for a high-risk Prostate Cancer. Legend: This figure shows a treatment plan and associated sentinel lymph node lymphangiography (SLNL) for a patient with locally advanced prostate cancer at a high risk of nodal involvement (Gleason 4 + 5). SLNL can identify sentinel lymph nodes and demonstrate lymph node drainage patterns, which can help practitioners decide on the extent of the nodal clinical target volume. Nodes identified by SLNL should be included in the clinical target volume. In the currently presented patient, a right external iliac sentinel lymph node was identified with no para-aortic sentinel lymph nodes. Hence, the clinical target volume was limited to a standard whole pelvic nodal volume. Doses to target volumes are depicted as 4500 cGy (green). (A) Planning CT (axial) with pelvic nodal volume depicted in blue and a potential right sentinel lymph node detected by SLNL in red. (B) SLNL (axial) with identified focus of uptake in the right pelvis side wall region identified with a red arrow. (C) Planning CT (coronal) showing the same involved external iliac node as seen in (A) and (B). (D) SLNL (coronal) with the same focus of uptake shown in (A) and (B) identified with a red arrow. The blue, yellow, and red contours are the clinical nodal volume, bladder, and prostate, respectively.

Role of choline-PET

BJUI
BJU INTERNATIONAL

[18F]fluoromethylcholine (FCH) positron emission tomography/computed tomography (PET/CT) for lymph node staging of prostate cancer: a prospective study of 210 patients

Mads H. Poulsen*§, Kirsten Bouchelouche†, Poul F. Høilund-Carlsen†§, Henrik Petersen†, Oke Gerke†, Signe Inglev Steffansen†, Niels Marcussen‡§, Niels Svolgaard*, Werner Vach¶, Ulla Geertsen* and Steen Walter*§

CONCLUSIONS

BJU Int. 2012 Apr 23

- Due to a relatively low sensitivity and a correspondingly rather low PPV, FCH PET/CT is not ideal for primary LN staging in patients with prostate cancer.
- However, FCH PET/CT does convey important additional information otherwise not recognised, especially for bone metastases.

Lymph Node Staging with Choline PET/CT in Patients with Prostate Cancer: A Review

Andrea Skanjeti[1] and Ettore Pelosi[2]

Conclusion: "To date, there are no concordant results on the role of choline PET in lymph node staging of patients with new diagnosis of prostate cancer…. However, it should be pointed out that in this setting, other imaging modalities are less accurate, and so PET represents the best non invasive choice. …... Finally, the evaluation of novel treatments has potential advantages from the use of choline PET…"

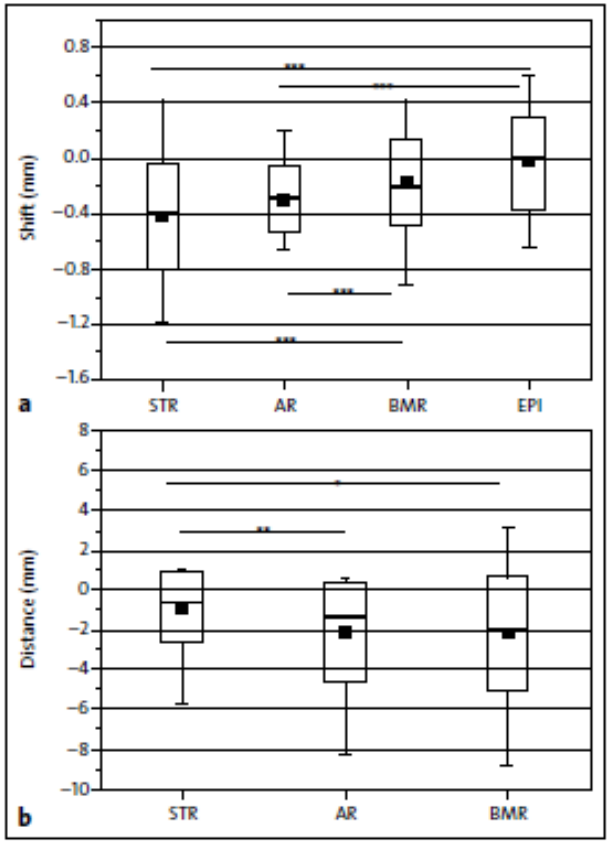
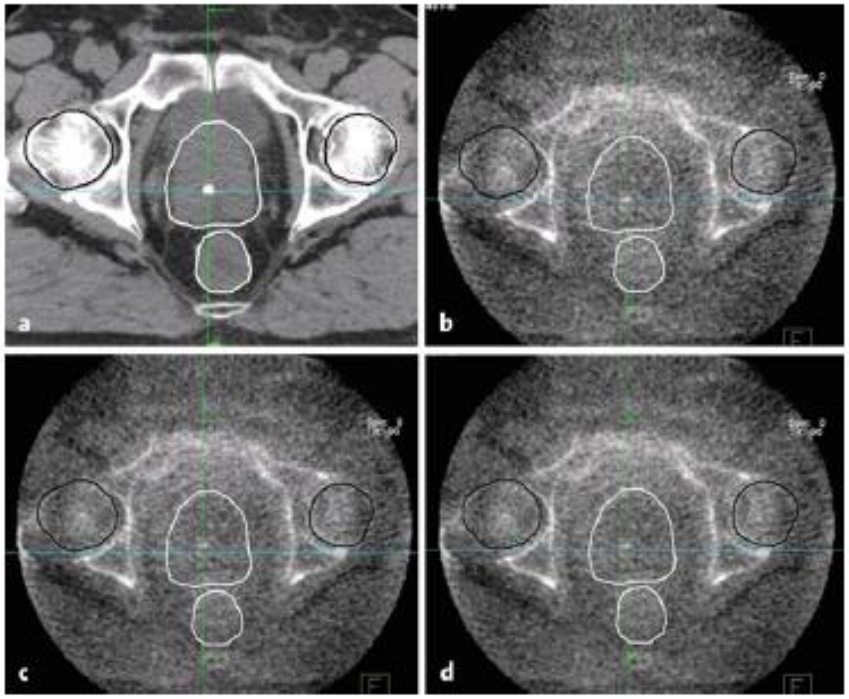
Prostate Image-Guided Radiotherapy by Megavolt Cone-Beam CT

Sergio Zucca, Barbara Carau, Ignazio Solla, Elisabetta Garibaldi, Paolo Farace, Giancarlo Lay, Gianfranco Meleddu, Pietro Gabriele[1]



Figures 1a and 1b. Patients shifts (**a**) and calcification displacements (**b**) along the AP axis, calculated by electronic portal imaging (EPI), and MV-CBCT after automated (AR), soft tissue (STR) and bone markers (BMR) registration. * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$.



Figures 2a to 2d. The contours of bone, prostate, and rectum were delineated on planning CT (**a**) and overlaid on the MV-CBCT after registration by manual soft tissue (**b**), manual bone landmark (**c**), and automated registration (**d**). A cross-line, centered on a calcification in the planning CT, was overlaid on the differently registered MV-CBCT. The distance between the cross-line and the calcification visible on MV-CBCT is clearly lower in (**b**) than in (**c**), particularly along AP direction. An intermediate distance was observed in (**d**).

Outline

1. Esiste una letteratura specifica sulla RT della malattia prostatica sicuramente estesa ai linfonodi?
2. Esiste una letteratura che associa una RT ipofrazionata con una WPRT?
3. Possibili soluzioni proposte dal punto di vista del livello tecnico (IMRT-SIB-IGRT con Linac vs stereotassi Linac vs cyberknife)
4. Quale il bilancio rischio-beneficio?
5. Il trattamento delle recidive linfonodali: problemi e soluzioni
6. Quali pazienti trattare
7. La nostra esperienza (2010-2013)
8. Riflessioni

Background

In these cases the standard treatment is OT until disease progression

But after?

Few therapeutic chances

Second line OT

Chemotherapy

Local therapies (thermoablation with RF, crioablation, surgery, RADIOTHERAPY)

Background

Local therapies particularly employed in order to posticipate as possible the use of OT

Quali pazienti trattare?

1. pazienti ad alto rischio
2. pazienti ad altissimo rischio con malattia linfonodale dimostrata mediante RM o PET colina
3. pazienti con recidiva di malattia linfonodale dopo precedente PR o RT a dosi radicali su P/VS
4. pazienti con malattia linfonodale dimostrata ed una lesione ossea (oligometastasi)
5. pazienti con recidiva di malattia linfonodale dimostrata ed una lesione ossea (oligometastasi)

Pazienti:

- in condizioni generali buone KI = 80-100
- Non malattie addominali in atto (RCU, M. Chron)
- non malattie epatiche/renali in atto
- complianti per trattamenti di circa 20 minuti (non dolore osseo)
- consenso informato

PROTOCOLLO CLINICO RADIOTERAPIA

ADAPTIVE 1.1

PATOLOGIA: Adenocarcinoma della prostata non operato ad alto, altissimo rischio

TITOLO: **Trattamento dell'adenocarcinoma prostatico ad Alto/Altissimo Rischio mediante Tomoterapia Elicoidale (HT)**

PRINCIPALI CRITERI DI INCLUSIONE UTILI PER LA STADIAZIONE:

1. Pazienti alto/altissimo rischio: >cT3a (o N+) e/o PSA > 20 e/o GS > 7 (8-10)
1. Esami ematologici, dosaggi del PSA ripetuti, esame urine completo, funzionalità epatica, renale, pancreatica
2. Esame istologico che conferma l'adenocarcinoma della prostata
3. Rx torace in 2 proiezioni e/o TC torace-addome
4. Scintigrafia ossea total body con ^{99m}TC
5. RM con endocoil della prostata
6. PET/CT con Colina in pazienti con sospetta diffusione loco-regionale di malattia (opzionale).
7. Consenso informato

TIPOLOGIA DI TRATTAMENTO:

Macchinario utilizzato: Tomotherapy HD

Durata del trattamento: 25 minuti a seduta per 32 sedute giornaliere, per un totale di sei settimane e mezza circa di trattamento

MEDICI STRUTTURATI DI RIFERIMENTO:

Pietro Gabriele (Direttore) pietro.gabriele@ircc.it
Elisabetta Garibaldi elisabetta.garibaldi@ircc.it
Elena Delmastro elena.delmastro@ircc.it

MEDICO NON STRUTTUTATO, RICERCATORE DI RIFERIMENTO:

Gabriella Cattari gabriella.cattari@ircc.it

DATA MANAGER DI RIFERIMENTO:

NOTE:

Studio di fase II dell'IRCCS di Candiolo – FPO (GIC urologico; Dir.: Dr. P. Gabriele)
La radioterapia è eseguita in associazione con due/tre anni di ormonoterapia (Servizio di Oncologia; Dir. M. Aglietta; oncologo responsabile di patologia: Cinzia Ortega cinzia.ortega@ircc.it)

PROTOCOLLO CLINICO RADIOTERAPIA

ADAPTIVE 1.4

PATOLOGIA: Adenocarcinoma della prostata, recidivo

TITOLO: **Protocollo di trattamento delle recidive da adenocarcinoma della prostata mediante Tomoterapia Elicoidale (HT)**

PRINCIPALI CRITERI DI INCLUSIONE UTILI PER LA STADIAZIONE:

- Pazienti con metastasi linfonodali (oligometastatici) con o senza recidiva locale
- Documentazione delle precedenti terapie eseguite (radioterapia, interventi chirurgici, ormonoterapie)
- Valutazione collegiale urologica
- PET/CT con Colina
- RM con endocoil (quando indicato)
- Scintigrafia Ossea Total Body con ^{99m}TC (quando indicato)
- Emocromo, enzimi epatici e pancreatici, azotemia, glicemia, creatinina, esame completo delle urine
- Consenso informato

TIPOLOGIA DI TRATTAMENTO:

Macchinario utilizzato: Tomotherapy HD o LINAC

Durata del trattamento: 25 minuti al giorno, per un totale di 30 sedute giornaliere in sei settimane e mezza circa di trattamento

MEDICI STRUTTURATI DI RIFERIMENTO:

Between October 2010 and June 2013, 93 patients with histologically confirmed high-very high risk prostate cancer or with nodal or distant metastatic disease were treated at IRCCS – FPO Cancer Institute of Candiolo, Torino, Italy, with definitive IMRT-SIB-IGRT technique using Tomotherapy ± ADT. Patients were stratified in high-very high risk and metastatic prognostic groups according to NCCN guidelines. Ten patients were lost at the follow-up and so the cohort of the study is composed by 83 patients assessable in terms of toxicity and outcome with a median follow-up of 14 months.

Trends in Cancer Research

Original Communication

A personalised treatment with image guided intensity modulated radiotherapy for high-very high risk and metastatic prostate cancer patients: Preliminary results

Elisabetta Garibaldi[1,*], Gabriella Cattari[1], Domenico Gabriele[4], Elena Delmastro[1], Barbara Carau[5], Claudia Cutaia[2], Sara Bresciani[2], Cinzia Ortega[3] and Pietro Gabriele[1]

[1]Radiotherapy, [2]Medical Physics and [3]Medical Oncology Units, IRCCS – FPO Candiolo, Torino, Italy, [4]Physiology Institute, Neuroscience Department, University of Torino, Italy, [5]Radiotherapy Unit, Businco Oncology Hospital, Cagliari, Italy

In our cohort a high percentage of patients was staged with MRI (71%) and with PET/CT (37%) allowing to disclose 20 N+ patients and 5 M+ patients. Thanks to the high RT doses delivered even in the metastatic sites, no patient has until now relapsed in the RT fields; however it should be taken into consideration that the result is only preliminary due to the short 14 months median follow-up and the ongoing ADT in a high percentage of patients. Acute and late toxicities are acceptable and, apart from nausea, no collateral effect has been observed on bowel or upper abdomen.

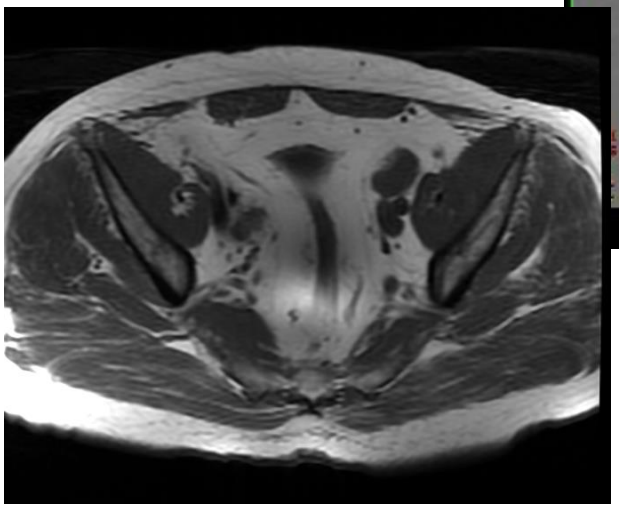
CONCLUSION

Our study shows the feasibility of wide field, high dose radiotherapy on high-very high and metastatic prostate cancer patients treated with radical intent in association with long term hormone-therapy; in fact irradiation included pelvic prophylactic nodes, positive nodes or distant metastasis if apparent, and in some patients also prophylactic lumbar-aortic nodes.

In our series we observed 2 recurrent patients, one of whom, with lumbar-aortic recurrence, was at diagnosis pelvic N1. We irradiated lumbar-aortic nodes only when imaging became positive in this area. Perhaps patients with pelvic N1 at diagnosis could benefit from a prophylactic lumbar-aortic irradiation. Studies are needed to define the utility of such irradiation.

Clinical case (GP)

- (GP) Patient 61 years old
- In August 2010 **PSA: 121** ng/ml
- September 2010: Prostate biopsy → adenoca, GS 8 (5+3)
- Bone scan: negative
- Endocoil-MRI & choline-PET: **cT3bN1** (external bilateral iliac and right common iliac N+)



Clinical case (GP)

Avec contrôle	20,9 (±3,0)	21,2 (±3,7)	18,8 (±4,6)	18,2 (±3,7)	15,8 (±3,1)
Sans contrôle	11,2 (±3,6)	NA	15,5 (±2,2)	NA	9,9 (±1,6)
Toutes	13,7 (±3,2)	21,0 (±3,9)	16,6 (±3,7)	18,3 (±3,9)	11,5 (±1,6)

Les données représentent les durées moyennes déviation standard (SR), exprimées en minutes. NA : non applicable.

[a] La modalité marqueur (avec imagerie portale) a été réalisée dans un seul centre. À titre comparatif, les durées des séances avec la modalité tomographie conique dans ce centre étaient les suivantes (en minutes) : avec contrôle 20,9 (±3,0) dans le bras hebdomadaire et 21,2 (±3,7) dans le bras quotidien ; sans contrôle 11,2 (±3,6) dans le bras hebdomadaire ; toutes séances confondues : 13,7 (±3,2) dans le bras hebdomadaire et 21,0 (±3,9) dans le bras quotidien.

Tableau 6
Durées cumulées moyenne de temps d'intervention du personnel.
Mean cumulative duration of personnel intervention (hours).

	Tomographie conique		Grains		Témoin
	Hebdomadaire	Quotidien	Hebdomadaire	Quotidien	
Manipulateur en électroradiologie	18,3 (±3,6)	28,0 (±5,2)	19,5 (±2,5)	22,2 (±2,0)	14,1 (±2,3)
Médecin	0,7 (±0,7)	2,0 (±1,6)	0,1 (±0,1)	0 (±0)	0,4 (±0,4)
Physicien	0,2 (±0,5	0,5 (±1,0)	0,1 (±0,2)	0,0 (±0,1)	0,1 (±0,1)

Les données représentent les durées moyennes (±SD) exprimées en heures.

Évaluation économique prospective de la radiothérapie guidée par l'image des cancers de la prostate dans le cadre du programme national de soutien aux thérapeutiques innovantes et coûteuses

Prospective economic evaluation of image-guided radiation therapy for prostate cancer in the framework of the national programme for innovative and costly therapies assessment

Latorzeff[n], A. Bossi[o], V. Beckendorf[p], E. Touboul[q], X. Muracciole[r], J.-M. Bachaud[s], S. Supiot[h], J.-L. Lagrange[t]

Results

Results. – The economical analysis included a total of 241 patients enrolled between 2007 and 2011 in seven centres, 183 in the randomized study (128 with CBCT and 55 with fiducial markers) and 58 in the control group. Compared to weekly controls, the average additional cost per patient of daily controls was €847 (CBCT) and €179 (markers). Compared to PI, the average additional cost per patient was €1392 (CBCT) and €997 (fiducial markers) for daily controls; €545 (CBCT) and €818 (markers) in case of weekly controls.

Conclusion

Conclusion. – A daily frequency for image control in IGRT and 3D images patient positioning control (IGRT) for prostate cancer lead to significant additional cost compared to weekly control and 2D imaging (PI). Long-term clinical assessment will permit to assess the medico-economical ratio of these innovative radiotherapy modalities.

Riflessioni e considerazioni conclusive

1. Nella malattia ad alto rischio la irradiazione della pelvi è basata sul corpo della letteratura: la IMRT è lo standard corrente; l'impiego di una IMRT-IGRT è raccomandata quando le dosi superano i 78 Gy
2. Nella irradiazione della malattia ad altissimo rischio (N+ pelvico / lomboartico) la IMRT-SIB-IGRT è in studio in varie Istituzioni in alternativa alla chemioterapia ed alla chirurgia (casi selezionati): i risultati sono comunque eccellenti
3. La re-irradiazione dei linfonodi è tecnica complessa che presuppone lo studio della precedente irradiazione ed un piano somma da valutare con accuratezza e senso del limite
4. Non si può prescindere da una valutazione rischio-beneficio e di costo
