XXV CONGRESSO NAZIONALE

AIRO 2015

PALACONGRESSI - Rimini, 7-10 novembre

From the pathology report, we extracted the prevalence rate of involvement of levels IB-V.

Then, for each nodal level we computed the negative predictive value (NPV) based on literature data of sensitivity/specificity for CT [Curtin et al, 1998]. SENS=0.88, SPEC=0.39

$$NPV = \frac{(\text{specificity})(1 - \text{prevalence})}{(\text{specificity})(1 - \text{prevalence}) + (1 - \text{sensitivity})(\text{prevalence})}$$

Here we report 1-NPV or the risk that a level that does not contain any node larger than 10 mm harbors subclinical disease.

91 pts, HPV pos

The only factor that showed an association with pathological involvement of level IB was the number of pathologically involved neck levels besides IB: none of the 47 patients with only one (other) level involved was found to harbor disease in ipsilateral level IB as opposed to 6/33 (18.2%) with two or more other levels involved (OR 22.4, 95% CI 2.5–2980, $p = 0.0026$).

HPV-OPC ipsilateral nodal levels

The present paper, that is the first one to focus on HPV positive patients only, provides the rationale for avoiding treatment of ipsilateral ‘ very low risk ’ (<5%) levels, that would include levels V and IB. The latter may qualify for elective irradiation only when two or more other levels are involved.

Level IV might also be spared when level III is negative on a ‘reliable ’ imaging study or when the negativity of level III is pathologically assessed.

CLINICAL PRACTICE GUIDANCE FOR RADIOTHERAPY PLANNING AFTER INDUCTION CHEMOTHERAPY IN LOCOREGIONALLY ADVANCED HEAD-AND-NECK CANCER

JOSEPH K. SALAMA, M.D.,* ROBERT I. HADDAD, M.D.,† MERRIL S. KIES, M.D.,‡ PAUL M. BUSSE, M.D., PH.D.,§ LEI DONG, PH.D.,‡ DAVID M. BRIZEL, M.D.,¶ AVRAHAM EISBRUCH, M.D.,|| ROY B. TISHLER, M.D., PH.D.,† ANDY M. TROTTI, M.D.,# AND ADAM S. GARDEN, M.D.‡

Results: Recommendations and guidelines emerged that emphasize up-front evaluation by all members of the head-and-neck management team, high-quality baseline and postinduction planning scans with the patient in the treatment position, the use of preinduction target volumes, and the use of full-dose RT, even in the face of a complete response.

Response adapted volume deescalation

Materials/Methods: Patients (pts) with measurable locally advanced head and neck squamous cell cancer received 2 cycles of IC (cisplatin, paclitaxel, with or without cetuximab and/or everolimus). Patients with “good” response (GR), defined as $\geq 50\%$ reduction in the sum of gross tumor diameters, received TFHX2 (paclitaxel, fluorouracil, hydroxyurea, and 1.5 Gy twice daily RT every other week) to 75 Gy with the planning target volume (PTV1) encompassing exclusively gross disease. Patients with $< 50\%$ response (NR) were treated with volumes encompassing PTV1 and the next nodal station at risk (PTV2) to 45 Gy, followed by a sequential boost to PTV1 to 75 Gy.

Fig. 2. Relation of the regression rate to the recurrence rate in the neck of patients who were treated with X rays to a dose of 70 Gy in 7 weeks (act.).

PROGNOSTIC VALUE OF THE REGRESSION RATE OF NECK NODE METASTASES DURING RADIOTHERAPY

HARRY BARTELINK, M.D., Ph.D.

A prospective study was carried out in order to assess whether the regression rate can be applied as a parameter, which could be correlated with the probability of recurrence after radiation of neck node metastases. Measurements were made on neck node metastases during the radiation treatment period in 47 patients. Tumors with a slow regression rate were shown to have a high probability of recurrence. The results indicate that accurate measurements of the regression rate provide prognostic information, which is obtained early enough for the radiotherapist to consider additional treatment.

FIGURE 3-3. The theoretical relationship is depicted for the number of 2-Gy fractions and the number of clonogens, for which the goal is to achieve 90% local control. The relationship was modeled by assuming a surviving fraction of 0.5 after each fraction (SF_2). The tumor control probability (TCP) is equal to e^{-SN} , in which S is the surviving fraction after F fractions ($S = [SF_2]^F$), and N is the clonogen number. The straight line is the relationship if the dose were a continuous variable.

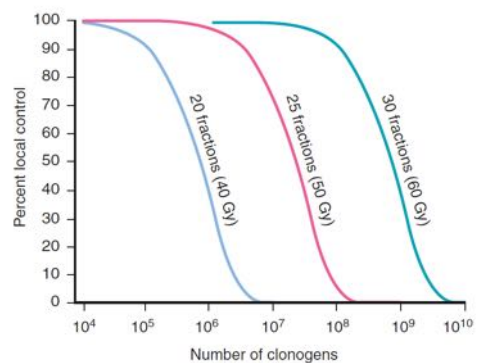

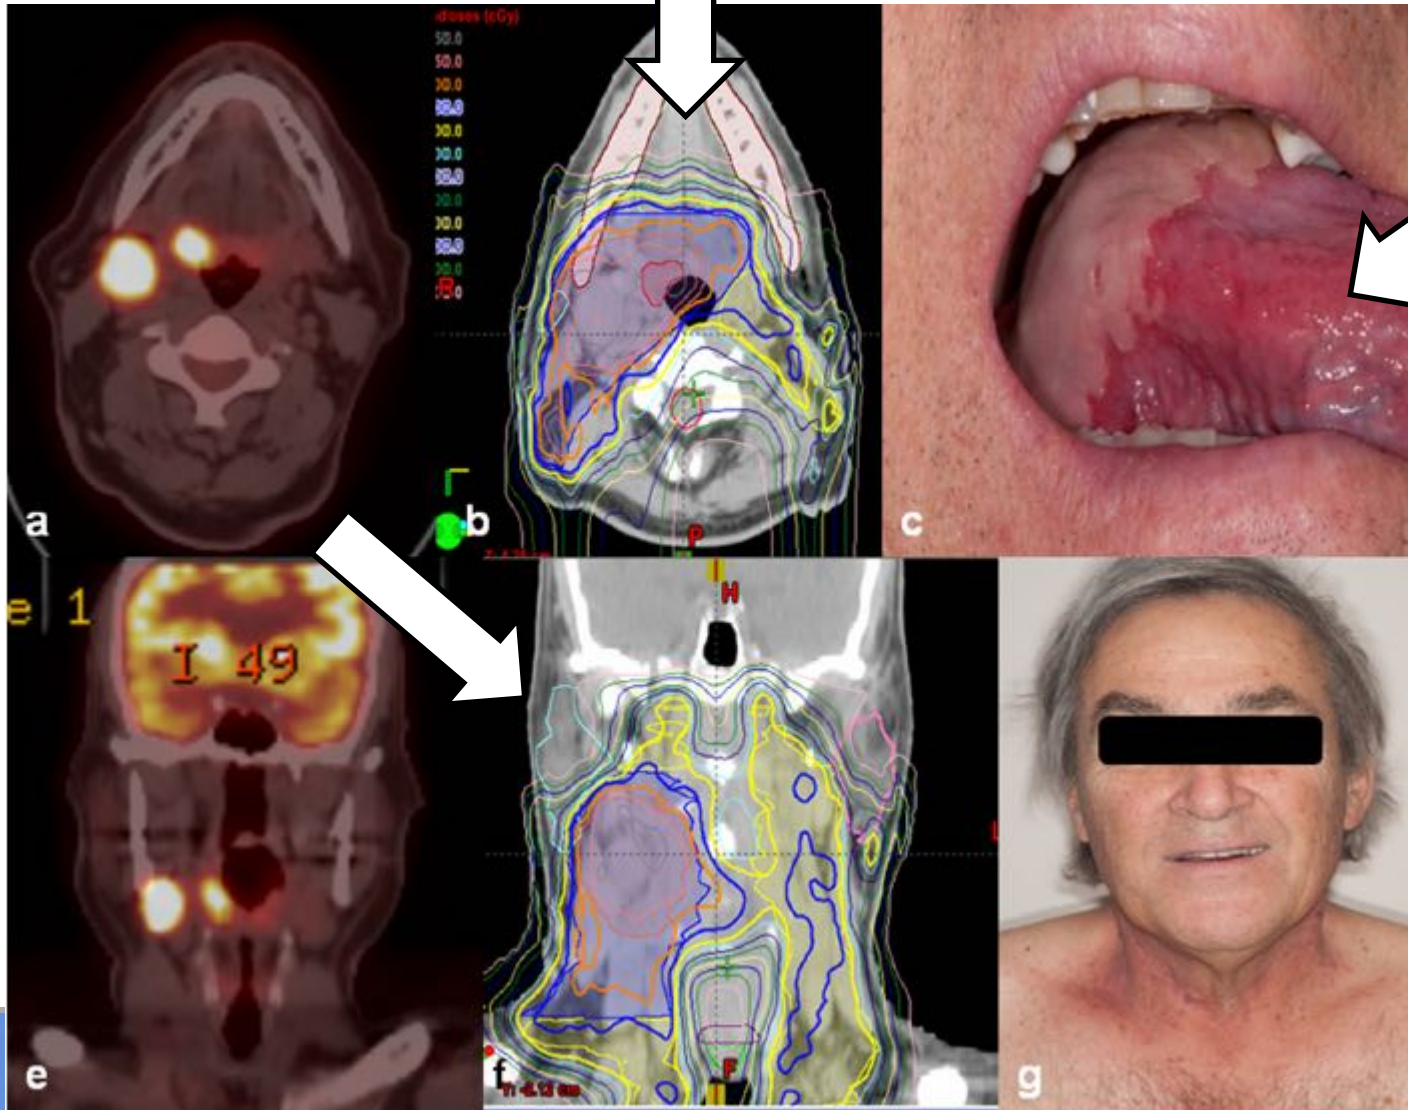

FIGURE 3-4. The theoretical relationship between local control and clonogen number is depicted for different total doses delivered at 2 Gy per fraction. The parameters are the same as in Figure 3-3.

- outcome of 196 pts w stage I NPC not electively in the neck;
- 53 pts (27%) subsequently failed in the neck, mostly upper neck
- nodal salvage rate was 81%
- however, OS was lower for pts who failed compared to pts who did not fail in the neck due to a higher incidence of DM (20% vs 3%)

Conclusions

- Indications and contouring guidelines are now available in the literature;
- Challenging indications and volumes developed empirically over decades is reasonable, but should be clinically driven
- For OPC, it is reasonable to consider avoiding the uppermost part of the contralateral uninvolved level II, as well as contralat levels IB (and V)
- For NPC, nodal volume de-escalation should be cautiously done
